This software and its documentation are copyright 2006 by the Broad Institute/Massachusetts Institute of Technology. All rights are reserved.

This software is supplied without any warranty or guaranteed support whatsoever. Neither the Broad Institute nor MIT can be responsible for its use, misuse, or functionality.
GenePattern provides access to a broad array of computational methods used to analyze genomic data. Its extendable architecture makes it easy for computational biologists to add analysis and visualization modules, which ensures that GenePattern users have access to new computational methods on a regular basis.

If you are new to GenePattern, begin with the basics:

- The **Concepts Guide** provides a brief introduction to GenePattern: its primary objects (modules, pipelines, suites) and its client-server architecture. All other GenePattern documentation assumes that you are familiar with these concepts.

- The **Tutorial** provides a hands-on introduction to the GenePattern Web Client. Many users find that this is all they need to begin using GenePattern.

If you are familiar with GenePattern and are looking for more information about the Web Client, this is the right guide:

Getting Started

This section describes how to start and exit from the GenePattern Web Client. It provides an overview of the user interface, including the navigation bar and pop-up menus.

- Installing GenePattern
- Starting the GenePattern Server
- Starting the GenePattern Web Client
- Exploring the User Interface
- Exiting from GenePattern
- Getting Help

Installing GenePattern

When you install GenePattern, you typically install all three components: the server, Web Client, and Desktop Client. GenePattern can be run standalone, or separated into its client and server components to take advantage of a more powerful compute server. A single installer works for either local or distributed configurations.

If you have not yet installed GenePattern, you can do so by following the installation instructions. If you are new to GenePattern, you may find it helpful to work through the GenePattern Tutorial before reading the more detailed information in this guide.

Starting the GenePattern Server

You must start the GenePattern server before you can start either the Web Client or the Desktop Client. The server takes several seconds to start; clients cannot connect to it while it is starting.

To start the GenePattern server, double-click the Start GenePattern Server icon, shown below. By default, installing GenePattern places this icon on your desktop.

On Windows, while the server is starting, a console window displays messages. The server is ready when the console displays a message similar to the following (version and build numbers depend on the version of the software that you have installed):

```
GenePattern server version 3.0 build 3.0.719 built Fri, Feb 9 2007 is ready.
```

On Mac OS X, while the server is starting, the server icon bounces in the Dock. The server is ready when the icon stops bouncing. If you want to read the messages, see the Console.

Starting the GenePattern Web Client

You must start the GenePattern server before you can start the Web Client.

To start the GenePattern Web Client:

1. Double-click the GenePattern Web Client icon, shown below. By default, the GenePattern installation places this icon on your desktop.

```
GenePatternHome.html
```

The Web Client login page appears:
2. Enter your user name and password. (If you do not have a GenePattern account, select Click to register.)
3. Click Sign In. The Web Client start page appears.

Exploring the User Interface

When you start the Web Client, the Web Client displays the start page. To return to this page, click the Modules & Pipelines item in the navigation bar or the GenePattern icon in the title bar.
The title bar includes:

- GenePattern icon: Click the icon to return to this page.
- My Settings: Click this link to modify your GenePattern account settings (see My Settings).
- Sign Out: Click this link to exit from the GenePattern Web Client.
- Your username: The GenePattern user name of the person currently logged into the Web Client.

The navigation bar provides access to Web Client pages and operations (see Navigation Bar).

The Modules & Pipelines pane lists the analysis modules and pipelines that you can run. Modules and pipelines not installed from the Broad repository are shown in red. Use the radio buttons to organize the modules and pipelines as you prefer:

- Category (default): Organizes analysis modules by functional category; pipelines are in the pipeline category. Each module is assigned to a category when it is created. To change the category, you must edit the module definition.
- Suite: Organizes modules and pipelines by suite. Suites are arbitrary collections of modules and pipelines. You can install suites from the Broad repository or create your own.
  For more information about a suite, click Suites>Manage to display all available suites. Click a suite name to display its definition. Click the icon next to a suite name to display a menu of commands for working with the suite (see Suites Menu).
- All: Organizes modules and pipelines alphabetically by name.

The center pane, which displays the welcome message, is the main display pane for the Web Client. The Web Client uses this pane to display information and to prompt you for input.

The Recent Jobs pane lists the most recent analyses that you have run and the results files generated by those analyses, as well as any currently running analyses. Click the icon next to a job or file name to display a menu of commands for working with the job or file (see Job Menu and File Menu).

The page footer provides two links:

- About GenePattern: Displays the release date and build number of your GenePattern server software.
- Contact Us: Displays a form that you can use to send questions and comments to the GenePattern team.

Note: If the URL of the Web Client is visible in your web browser, it points to the GenePattern server that you are using. The Web Client remains connected to the server throughout the session. The modules, pipelines and suites displayed in the Web Client are those installed on the server. When you run a module or pipeline, the Web Client runs the analysis on the server and stores the analysis results files on the server.

**Navigation Bar**

The navigation bar, which appears on most Web Client pages, provides access to Web Client pages and operations. Click a link in the table to go to the section of this guide that describes that operation.

**Job Results**
Display the Results Summary page.

**Results Summary**
Display jobs run on the server; delete jobs.

**Resources**
Display an overview of the resources.

- **Mailing List**
  Display the form you use to join a low-traffic GenePattern mailing list.

- **Report Bugs**
  Display the form you use to contact the GenePattern team to report bugs, provide feedback, or ask questions.

- **User Forum**
  Display the Yahoo GenePatternUserGroup page, which you can use to contact other GenePattern users.

**Downloads**
Display an overview of the available downloads.

- **Install Desktop Client**
  Download and install the Desktop Client software.

- **Programming Libraries**
  Download and install GenePattern libraries for use with Java, MATLAB, or R.

- **Public Datasets**
  Download sample datasets for use with GenePattern.

**Administration**
Display the Server Settings page.

- **Server settings**
  Modify settings that affect the GenePattern server.

**Help**
Display the Web Client start page.

- **Tutorial**
  Display the Tutorial, which provides a hands-on tour of the Web Client and Desktop Client.

- **Desktop Client Guide**
  Display the Desktop Client Guide, which describes the Desktop Client and how to use it.

- **Web Client Guide**
  Display this guide, which describes the Web Client and how to use it.

- **Programmers Guide**
  Display the Programmers Guide, which provides guidelines for writing modules and instructions for accessing GenePattern from the Java, MATLAB, and R programming environments.

- **Module Documentation**
  Display a list of the modules and pipelines installed on your server, with brief descriptions and links to the module/pipeline documentation.

- **File Formats**
  Display the File Formats Guide, which describes all file formats and provides instructions for creating input files.

- **Release Notes**
  Display the Release Notes, which describes new features and known issues in this release.

- **FAQ**
  Display the GenePattern list of Frequently Asked Questions.

**Job Menu**
When the Web Client displays an analysis job and its results, click the icon next to the job name to display a menu of commands for working with that job. For more information, see Working with Analysis Results.

- **Download**
  Download a zip file containing all analysis results files for this job.

- **Reload**
  Display the analysis and its parameters in the center pane, with the parameters set to the values used for this analysis job.

- **Delete**
  Delete the analysis job and its analysis results files from the GenePattern server.

- **Info**
  Display the parameter values and the analysis results files for this job.

- **View Java Code**
  Display the command line that you would use to run this job in the Java, MATLAB, or R programming environments. These commands are useful for programmers who want to access GenePattern from one of these programming environments or from...
their own applications.

**File Menu**

When the Web Client displays an analysis job and its results, click the icon next to the file name to display a menu of commands for working with that file. For more information, see [Working with Analysis Results](#).

- **Delete**
  - Delete the file from the GenePattern server.

- **Save**
  - Download the file from the GenePattern server.

- **Create Pipeline**
  - Create a GenePattern pipeline that includes the modules and parameters necessary to reproduce this results file.

- **List of modules**
  - List modules that commonly use this type of file as an input parameter. Select an analysis to display its parameters in the center pane, with this results file specified as the first input parameter.

**Suites Menu**

When the Web Client displays a suite, click the icon next to the suite name to display a menu of commands for working with that suite. For more information, see [Working with Suites](#).

- **Edit**
  - Available only for suites that you have created. Display the Edit GenePattern Suite page, which you can use to modify your suite.

- **Delete**
  - Delete the suite from the GenePattern server.

- **Export excluding dependents**
  - Create a zip file that contains the definition of the suite, but not the modules or pipelines in the suite. The zip file can be used to install the suite on another GenePattern server (see [Exporting and Installing Suites Using Zip Files](#)). Installing the suite from this zip file will not install any modules or pipelines in the suite; they must already be installed on the GenePattern server or be installed separately.

- **Export including dependents**
  - Create a zip file that contains the definition of the suite, as well as the modules and/or pipelines in the suite. The zip file can be used to install the suite on another GenePattern server (see [Exporting and Installing Suites Using Zip Files](#)). Installing the suite from this zip file will also install the modules and pipelines in the suite (unless they are already installed on the GenePattern server).

**My Settings**

The first time you log into a GenePattern server, the server creates a GenePattern account for you. Use *My Settings* to change your account information:

2. From the left pane, select the information that you want to modify. The Web Client displays the related page.
3. Modify and save your account information.
4. Optionally, return to step 2 to make additional changes.
● **Change Password**: Change the password for your GenePattern account on this server.

1. Enter your current password.
2. Enter your new password.
3. Reenter your new password for verification.
4. Click **Save**.

**Note**: By default, GenePattern does not require passwords. For information about enabling password protection, see [User Authentication](#).

● **Change Email**: Change the email address for your GenePattern account on this server.

```
<table>
<thead>
<tr>
<th>Current Email</th>
<th>No email set</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Email</td>
<td></td>
</tr>
<tr>
<td>Confirm New Email</td>
<td></td>
</tr>
</tbody>
</table>
```

1. Enter your new email address.
2. Reenter your new email address for verification.
3. Click **Save**.

The GenePattern server uses your email address for the following:

- When you run a module or pipeline, the Web Client sends the job to the GenePattern client and displays the Job Status page. On that page, you can click the **email notification** check box to have the Web Client send you email when the job completes.
- If you forget your password and request a new password, the Web Client sends your new password to this email address.
● **Visualizer Memory**: Specify the Java virtual machine configuration parameters (such as VM memory settings) to be used when running visualization modules. By default, this option is used to specify the amount of memory to allocate when running visualization modules (-Xmx512M).

![Java Flags: -Xmx512M](image)

![Save](image)

● **History**: Use this option to specify the number of recent analyses listed in the Recent Jobs pane on the Web Client start page.

![Display this many recent jobs: 4](image)

![Save](image)

The recent history size sets the maximum number of recent jobs in the right panel of the start page.

### Exiting from GenePattern

To exit from GenePattern:

1. Exit from the Web and Desktop clients.
   - To exit from the GenePattern Web Client, click **Sign Out** in the top right corner of the title bar.
   - To exit from the GenePattern Desktop Client, if it is running, select **File>Quit**.
2. Shutdown the server by double-clicking the Stop GenePattern Server icon, shown below. **Alternative**: If you are using Windows, you can simply close the console window.

![StopGenePatternServer](image)

On Windows, when you shutdown GenePattern, the GenePattern console window closes. On Mac OS X, the GenePattern server icon disappears from the Dock. On Linux machines, the GenePattern server exits silently.

If a GenePattern client remains running after you shutdown the server, the client displays error messages as it attempts to contact the server.

### Getting Help

The [GenePattern web site](https://genePattern.org) provides an overview of GenePattern and its analysis modules, as well as links to the GenePattern software and documentation. The documentation is your primary source for help with GenePattern:

- The **Concepts Guide** provides a brief introduction to GenePattern: its primary objects (modules, pipelines, suites) and its client-server architecture. All other GenePattern documentation assumes that you are familiar with these concepts.
- The **Tutorial** provides a hands-on tour of the Web Client and Desktop Client.
- The **Desktop Client Guide** describes the Desktop Client and how to use it.
- The **Web Client Guide**, this guide, describes the Web Client and how to use it.
- The **Programmers Guide** provides guidelines for writing modules and instructions for accessing GenePattern from the Java, MATLAB, and R programming environments.
- The **Modules** page lists the modules and pipelines in the Broad repository, with links to their documentation.
- The **File Formats Guide** describes all file formats and provides instructions for creating input files.
- The **Release Notes** describe new features and known issues in this release.
- **Frequently Asked Questions** answers common questions about GenePattern.
Running Modules and Pipelines

An analysis module runs a single analysis. A pipeline runs a series of analysis modules. If you are unfamiliar with GenePattern modules and pipelines, see the Concepts Guide.

- Running an Analysis Module or Pipeline
- Entering Parameters
- Checking Analysis Results
- Rerunning an Analysis

Running an Analysis Module or Pipeline

You can run an analysis module or pipeline in two ways:

- From the Modules & Pipelines pane of the Web Client start page.
- From the File menu of an analysis results file. This method has the benefit of chaining the current analysis to the previous analysis, which can be useful for creating pipelines (see Creating Pipelines).

To run an analysis module or pipeline:

3. Select the module or pipeline to run in one of two ways:
   - In the Modules & Pipelines pane, select the analysis to run. The analysis parameters appear in the center pane.
   - From the Recent Jobs pane (or the Results Summary page), click the icon next to an analysis results file and select a module to run. The analysis parameters appear in the center pane. The first input file parameter is set to the analysis results file.

4. Enter values for the parameter fields (see Entering Parameters).

5. Click Run to start the analysis. The Web Client sends the analysis job to the GenePattern server and displays the Job Status page. When the GenePattern server completes the job, the Web Client displays the results on the Job Status page (see Checking Analysis Results). How long a job takes to complete depends on the size of your dataset and the analysis that you are running.

6. Click Return to Modules & Pipelines Start to return to the Web Client start page. The Recent Jobs pane shows the analysis job that you just ran.

Visualizers: Unlike most modules and pipelines, visualizers run on the GenePattern client rather than the server. When you run a visualizer, the Web Client starts the visualizer and displays the status page. Visualizers do not generate results files. Because visualizers do not run on the server, they do not appear in the Recent Jobs pane.

Modules run from a pipeline work exactly the same as those run directly from the Web Client. If you run a visualizer from a pipeline, it gets displayed just as if you ran it directly from the Web Client. Analysis results files generated by a pipeline are exactly the same as those generated by modules run directly from the Web Client.

Entering Parameters

When you select a module or pipeline to run, the Web Client displays the parameters for the analysis:
The parameter form is similar for all modules and pipelines:

- The form lists each parameter followed by an entry box for the parameter value. Most modules have parameters; most pipelines do not.

- Below each parameter is a brief description of that parameter. Use the *Show parameter descriptions* check box at the top of the form to hide and show the descriptions.

- Required parameters are marked by an asterisk (*). Other parameters are optional.

- When a parameter requires a file name, you can enter it in many ways:
  - Click *Browse* (next to the file parameter box) to display the file selection window. Navigate to the desired file, select it, and click *Open*. Leave the *Upload File* radio button selected.
  - From the Recent Jobs pane, click the icon next to an analysis results file of the desired type and select *Send To parameter-name*. Leave the *Specify URL* radio button selected. This has the benefit of chaining this analysis to the previous analysis, which can be useful for creating pipelines (see *Creating Pipelines*).

- At the top and bottom of the form, are the following options:
  - **Run**: Starts the analysis.
  - **Reset**: Resets all parameters to their default values.
  - **Properties**: Displays the module or pipeline definition form. The module definition form lists the program that implements the analysis. The pipeline definition form lists the modules run by the pipeline.
  - **Export**: Creates a zip file that contains the module or pipeline definition. The zip file can be used to install this module or pipeline on another GenePattern server.
  - **Edit**: Available only for modules that you have created. Displays the Update Module form, which allows you to update your module.
  - **Help**: Displays the module or pipeline documentation.

- At the bottom of the form, the *View Code* field displays the code (Java, MATLAB, or R) used to run the module with the parameters that you have entered. This can be useful for programmers writing batch procedures or new modules.
Checking Analysis Results

When you run a module or pipeline, the Web Client sends the analysis job to the GenePattern server and displays the job status page.

When you start an analysis, the Web Client sends the analysis job to the GenePattern server and displays the Status page. When the analysis completes, the Web Client updates the page to list the analysis results files. Analysis results are stored on the GenePattern server for a period of time (by default, one week) and then deleted. The text shown in a bold red font tells you when the analysis results will be deleted.

From the status page, while the analysis job is running, you can:

- Select the email notification check box to have the GenePattern server send you email when the analysis is finished. If you are running an analysis that may take an extended period of time, select this check box and continue with other work. You can run other analyses or exit from the Web Client. The GenePattern server continues to work on the analysis job and sends you email when it is finished. When you receive the email, start the Web Client and review the analysis results.
- Click **Stop** to cancel the job.

After the analysis job is finished, the Web Client displays the analysis results files and you can:

- Click an analysis results file to display the file in a text viewer.
- Click **Download** to copy the selected files from the GenePattern server to your own directories. To select a file, select the check box next to it.
- Click **Delete** to delete the selected files from the GenePattern server. To select a file, select the check box next to it.
- Select/clear the **show execution logs** check box to show/hide the execution log files.

Click **Return to Modules & Pipelines Start** to return to the Web Client start page. The job and its results files are displayed in the Recent Jobs pane of the Web Client start page and on the Results Summary page. The file commands on the status page are also available in the Recent Jobs pane (see Exploring the User Interface) and on the **Job Results>Results Summary** page (see Job Results Page).

Rerunning an Analysis

To rerun an analysis:

- Select the analysis module or pipeline.
- Click the **Run** button.
- Repeat the analysis as necessary.
1. Display your analysis jobs in one of two ways:
   • Click Modules & Pipelines to display the Web Client start page, where your most recent jobs are listed in the Recent Jobs pane.
   • Click Job Results>Results Summary to display the Job Results page, which lists all of your analysis jobs.
2. Click the icon next to the analysis job that you want to rerun and select Reload. The analysis parameters appear in the center pane set to the values that were used for this analysis job.
3. Optionally, modify the parameter values.
4. Click Run.

**Working with Analysis Results**

When you run a module or pipeline, GenePattern runs the analysis job on the GenePattern server. Analysis results are stored on the GenePattern server for a period of time (by default, one week) and then deleted. If you are unfamiliar with how GenePattern runs modules and pipelines, see the Concepts Guide.

The following table summarizes the different ways you can work with analysis results:

<table>
<thead>
<tr>
<th>Displaying analysis results</th>

</tr>
</tbody>
</table>
Displaying Analysis Results

When you run a module or pipeline, the files generated by the module/pipeline are stored on the GenePattern server. The module author determines the content and format of the generated files; however, by convention, each module generates the following files:

- **Analysis results files** are typically formatted text files that contain the results of the analysis. Most analysis results files are intended to be used as input to subsequent analyses. Although these files can be viewed in a text viewer, the amount of information in the files may make them difficult to read.

  If an analysis module generates an analysis results file that requires examination and interpretation, there is generally a corresponding visualization module that you can use to display the results. Visualization modules have “Viewer” in the title. For example:

  ▪ Results from ComparativeMarkerSelection are viewed using the ComparativeMarkerSelectionViewer
  ▪ Results from modules in the Prediction category are viewed using the PredictionResultsViewer
  ▪ Results from SOMClustering are viewed using the SOMClusteringViewer
  ▪ Gene expression datasets are often viewed using the HeatMapViewer

- **Execution log files** are text files that describe how the analysis was run. A module might generate one or more of the following log files:

  ▪ `gp_task_execution_log.txt`: contains the parameter values used to run the analysis, which is useful for reproducing analysis results.
  ▪ `stdout.txt`: contains "standard output" messages; that is, comments generated as the analysis module runs.
  ▪ `stderr.txt`: contains "standard error" messages; that is, information about errors (if any) that occurred during the analysis.

  Log files can be viewed using a text viewer.

To display analysis results:

1. Display your analysis jobs in one of two ways:
   - Click **Modules & Pipelines** to display the Web Client start page, where your most recent jobs are listed in the Recent Jobs pane (see Exploring the User Interface).
   - Click **Job Results>Results Summary** to display all of your analysis jobs (see Job Results Page).

   For each job, the Web Client lists all files stored on the server for that job.

2. To display an analysis results files in a visualization module, click the icon next to the file and select the module to use. GenePattern displays the analysis parameters in the center pane. The first input file parameter is set to this analysis results file.

3. To display an analysis log file in a text viewer, click the file name.

Job Results Page

When you run a module or pipeline, the analysis job is run on the GenePattern server and the analysis results are stored on the server. The Recent Jobs pane of the Web Client start page lists your most recent analysis jobs and their analysis results (see Exploring the User Interface). The Job Results page lists all your analysis jobs and their analysis results.

To display the Job Results page, click **Job Results>Results Summary**:
From this page, you can

- View the jobs run on your GenePattern server. To view only your own jobs, clear the show everyone’s modules check box. To view all jobs, select the check box.
- View the results files for each job:
  - Most modules generate both analysis results files and execution log files. To display only the analysis results files, clear the show execution logs check box. To display all generated files, select the check box.
  - Click open all or close all to expand all jobs (displaying both jobs and their generated files) or collapse all jobs (displaying only the jobs and hiding their generated files).
- Delete jobs and/or results files from your GenePattern server. Deleting a job deletes all of its results files.
- Sort the jobs and/or files:
  
  1. Use the drop-down lists to select the job and file attributes to use for the sort.
  2. Use the up and down arrow next to each drop-down list to select the sort order (ascending or descending).
  3. Click Sort.

For each job, the Web Client displays similar information:

- Job number.
- Name of the module or pipeline that was run. Click the icon following the job name to display the job menu.
- List of generated files stored on the GenePattern server. For each file:
  - File name. Click the icon following the file name to display the file menu.
  - Size of the file.
  - Date and time the file was created.
Click the icon to the left of the job name to hide/show the generated files.
Analysis and visualization modules are at the heart of GenePattern. **Analysis modules** provide computational methods and tools for gene expression analysis, proteomics data analysis, SNP analysis, and data preprocessing and conversion. **Visualization modules** display your data and analysis results graphically. If you are unfamiliar with GenePattern modules and pipelines, see the [Concepts Guide](#).

The following table summarizes the different ways you can work with GenePattern modules.

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display module definitions</td>

### Module Definition Page

To display the definition of a module:

1. Click Modules & Pipelines to display the Web Client start page.
2. Select the module to display.
3. When the Web Client displays the module parameters, click Properties. The Web Client displays the module definition page, as shown below.
The module definition page is a read-only version of the page used to create and edit the module. The field descriptions below are presented in two parts: a brief description of the field, which is generally sufficient if you are viewing the module definition, and additional details, which are necessary if you are creating or editing the module definition.

- **Name.** Name of the module.
  
The name of the module is used to identify the module in the user interface of the GenePattern clients. The name should be a short but descriptive, without spaces or punctuation, and may include both upper- and lower-case characters.

  Example: ConsensusClustering

- **LSID.** The Life Science Identifier (LSID) used to uniquely identify a GenePattern module.
  
  You cannot create or edit LSIDs. The GenePattern server automatically assigns an LSID to each version of a module. If you are unfamiliar with GenePattern versioning, see the Concepts Guide.

- **Description.** Brief description of the module.
  
  GenePattern displays the description, sometimes in abridged form, in forms and drop-down lists in the clients and in generated code when creating scripts from pipelines. The description should be a sentence or short paragraph that documents succinctly what your module does and why someone would want to use it.

  Example from ConsensusClustering: Resampling-based clustering method

- **Author.** The author's name and affiliation (company or academic institution).
GenePattern displays the author name as part of the module definition. This is a comment-only field. If you share this module, the author field allows other users to credit the author when citing the module and to contact the author with questions, suggestions, or enhancement ideas.

Example from ConsensusClustering: Stefano Monti, Broad Institute

- **Privacy.** Modules may be marked as public or private:
  - Public modules may be accessed by anyone using the GenePattern server.
  - Private modules may be accessed only by the person who installed or created the module (or by an administrator).

  When you create a module, by default, it is marked private. When you are ready for others to use your module, change the privacy to public.

- **Quality level.** One of three terms that indicates the author’s confidence in the robustness of the module: development, preproduction, and production.

  When you create a module, by default, its quality level is development. Although these terms have no strict definitions, they are useful for setting user expectations. If you share this module, set the quality level appropriately.

- **Command line.** Command line used to launch the module. Values enclosed in angle brackets are replaced by specific values before the command executes.

  When you create/update a module, the command line is critical and must be platform-independent. You define the command line as a combination of fixed and dynamic text. GenePattern resolves the dynamic text to build the command line that executes the module. For more information, see Defining the Module Command Line.

- **Module type.** Category name assigned to this module, which is used to organize modules and pipelines. Pipelines are always assigned to the category name pipeline.

  When you create/update a module, you can choose an existing category name or create a new category name. If your module fits into an existing category, such as Preprocess & Utilities, select that category from the drop-down list; otherwise, click the New button to add a new category. The Web Client creates the drop-down list of categories dynamically based on the categories of the modules installed on your GenePattern server. If you delete the last module in a given category, that category is removed from the drop-down list.

- **CPU type.** Indicates the type of CPU required to run the module, or any if the module runs on any type of CPU.

  When you create/update a module, if your code is compiled for a specific platform (Intel, Alpha, PowerPC, etc.), select that platform from the drop-down list. GenePattern enforces CPU requirements when it runs the module.

- **Operating system.** Indicates the operating system required to run the module, or any if the module runs on any operating system.

  When you create/update a module, if your code requires a specific operation system (Windows, Linux, MacOS, etc.), select that operating system from the drop-down list. GenePattern enforces operating system requirements when it runs the module.

- **Language.** Indicates the programming language used to implement the module.

- **min. language version.** Indicates the version of the programming language used to implement the module.

  GenePattern does not enforce programming language requirements. However, including the language version information in the module definition gives prospective users a hint concerning system requirements.

- **Version comment.** Describes changes made to the module in this version.

  When you update a module, briefly describe the changes that you have made. When GenePattern clients display a drop-down list of versions, the comments for each version are visible in the drop-down list.

- **Output description.** Lists the file formats of the output files generated by the module.

  When you create/update a module, use the File format(s) field to select all output file formats generated by your module. To select multiple file formats from the list, use ctrl-click or shift-click. If your module generates an output file format not included in the list, click the New button to add that file format to the list.

- **Current files:** Lists the support files packaged with the module.

  When you create/update a module, you must specify all files used in your module, including scripts, libraries, property files, DLLs, executable programs, documentation, and so on. For more information, see Adding Module Support Files.

- **Parameters:** Lists the module parameters.
When you create/update a module, you must define each parameter in the module command line. For more information, see Defining the Module Parameters.

Defining the Module Command Line

Defining the command line that launches your module is a critical piece of defining your GenePattern module. The text of the command line must be variable to address different parameter values, CPU platforms, and operating systems. To ensure that your module runs under different conditions, the command line that you enter on the module definition page will be a combination of fixed and variable text. You specify the variable text in the form of substitution variables enclosed in angle brackets. GenePattern replaces the substitution variables with their assigned values before invoking the command.

Use substitution variables to reference:

- Module parameters. To define module parameters, use the Parameters section of the module definition form. To reference a module parameter in the command line, enter the parameter name enclosed in angle brackets; for example, <filename>. Each parameter defined in the Parameters section must be mentioned in the command line, unless you have specified that it is an optional parameter. If you provide a default value for a parameter, the default value is used when a user invokes the module and fails to specify a value for the parameter.

- Server configuration properties. To set server configuration properties or create new server configuration properties, select Administration>Server Settings and edit the Custom settings, as described in Modifying Server Settings. For a complete list of server configuration properties, see the GenePattern/resources/genepattern.properties file. To reference a configuration property in the command line, enter the property name enclosed in angle brackets; for example, <libdir>.

- Java system properties. For more information about these properties, see Java system properties. To reference a Java system property in the command line, enter the property name enclosed in angle brackets.

- Programming environment path names. GenePattern provides three server configuration properties, <java>, <perl>, <R>, that resolve to the full path names for Java, Perl, and R. These are the three languages used to build the modules currently provided in the Broad repository. If your program is run by another interpreter, such as Python or LISP, you can use an absolute pathname (for example, /usr/bin/python) or create a configuration property for the interpreter pathname (for example, python=/usr/bin/python). If your program is an executable file, you do not need an interpreter, so do not need such a property. To create a server configuration property, select Administration>Server Settings and edit the Custom settings, as described in Modifying Server Settings.

The following table lists the substitution variables for the most commonly used server configuration properties:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;java&gt;</td>
<td>path to Java; usually the one running the GenePattern server</td>
</tr>
<tr>
<td>&lt;perl&gt;</td>
<td>path to Perl, installed with GenePattern server on Windows, otherwise the one already installed on your system</td>
</tr>
<tr>
<td>&lt;R&gt;</td>
<td>path to a program that runs R and takes as input a script of R commands. R is installed with the GenePattern server on Windows and MacOS</td>
</tr>
<tr>
<td>&lt;java_flags&gt;</td>
<td>Java virtual machine configuration parameters (such as VM memory settings) from the Server Settings page (Java Flag settings)</td>
</tr>
<tr>
<td>&lt;libdir&gt;</td>
<td>directory where the module's support files are stored</td>
</tr>
<tr>
<td>&lt;job_id&gt;</td>
<td>job number</td>
</tr>
<tr>
<td>&lt;name&gt;</td>
<td>name of the module being run</td>
</tr>
<tr>
<td>&lt;filename_basename&gt;</td>
<td>for each input file parameter, the filename without the file extension or directory</td>
</tr>
</tbody>
</table>

Note: In the property name, filename is the name of the input file parameter. For example, if you have an input file parameter named input.filename, the substitution property name is <input.filename_basename>. The next two properties are similar.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;filename_extension&gt;</td>
<td>for each input file parameter, the extension without the filename or directory</td>
</tr>
<tr>
<td>&lt;filename_file&gt;</td>
<td>for each input file parameter, the input filename without the directory</td>
</tr>
<tr>
<td>&lt;path.separator&gt;</td>
<td>Java classpath delimiters (: or ;), useful for specifying a classpath for Java-based modules</td>
</tr>
<tr>
<td>&lt;file.separator&gt;</td>
<td>/ or \ for directory delimiter</td>
</tr>
</tbody>
</table>
<line.separator> newline, carriage return, or both for line endings

<user.dir> current directory where the job is executing

<user.home> user's home directory

<parameter_name> value of the named parameter; for example, if you have a parameter named arg1, use the substitution property <arg1> to include the value of that parameter on the command line

The following example uses substitution variables for two configuration properties, <java> and <libdir>, and one module parameter, <arg1>:

<java> -cp <libdir>mymodule.jar com.foo.MyModule <arg1>

To execute the module, GenePattern locates the Java runtime and asks to execute the MyModule class using code from the module support file mymodule.jar. The value of the arg1 parameter is passed as an argument to MyModule.

Note: if your module is designed to accept a standard input stream and/or write to a standard output stream, you can use redirection syntax when describing the command line. To redirect a file to the input stream, enter the text `< followed by the input file parameter. To redirect the standard output or standard error streams to a named file, enter the text `>` or `|>` followed by the name of the output file. In the following example, the LogTransform module reads its input from the standard input stream and writes its output to the standard output stream:

<perl> <libdir>log_transform.pl `< <input.filename> `> <output.file>

Defining the Module Parameters

When you create/update a module, you must define each module parameter. GenePattern uses the definition that you supply to prompt users for input when they run your module. Use the Parameters section of the Create/Update module form to enter each parameter. Every parameter entered in this section must appear in the command line, unless you mark the parameter as optional.

Parameters: The names of these parameters will be available for the command line (above) in the form <name>.

<table>
<thead>
<tr>
<th>name</th>
<th>description (optional)</th>
<th>choices</th>
<th>default value</th>
<th>optional</th>
<th>when specified</th>
<th>type</th>
<th>format</th>
</tr>
</thead>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Following are descriptions of each field. The first line of the Parameters section provides an example parameter.

- Name. Parameter names may include upper- or lower-case characters, numbers, and periods as a separator character between "words". In the command line, reference the parameter name in angle brackets (<name>) to indicate that the value of that parameter should be substituted at that position. The GenePattern clients use the
parameter name to prompt the user for the parameter value. When using the programming language
environments, parameter names are used to identify the parameters in the function calls.

- **Description.** The description field is optional, but very useful for users of your module. When the GenePattern clients prompt users for module parameters, they display the description of each parameter. It is particularly helpful to provide information such as what the parameter is used for, whether it interacts with other parameters, and any reasonable range of values.

- **Choices.** Some parameters are best represented as a drop-down list of choices. By constraining input to those from the list, the user is saved typing and cannot make a mistake by choosing an invalid setting (unless there is a dependency on some other parameter). The entry in the choices field is a simple semi-colon delimited set of choices.

But what if you want the user to be able to choose "human-readable" choices yet have the program accept the same ugly or complicated commands that it always has? No problem. Each choice may have a command-line component (which will be on the left) and a human-readable component (on the right), separated by an "=". The following example

```
hierarchical=Hierarchical clustering;SOM=Self-organizing map;NMF=Non-negative Matrix Factorization;=nothing specified;3.14159265=pi
```

creates a drop-down list that contains the following choices:

<table>
<thead>
<tr>
<th>Choices</th>
<th>Associated command-line component</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchical clustering</td>
<td>hierarchical</td>
</tr>
<tr>
<td>Self-organizing map</td>
<td>SOM</td>
</tr>
<tr>
<td>Non-negative Matrix Factorization</td>
<td>NMF</td>
</tr>
<tr>
<td>nothing specified</td>
<td></td>
</tr>
<tr>
<td>pi</td>
<td>3.14159265</td>
</tr>
</tbody>
</table>

- **Default value.** Specify a default value to be supplied on the module’s command line in cases where the user does not supply a value when invoking the module. This is not the same as the module’s own internal defaults. Instead, this allows the GenePattern module declaration author to create a default, even when none exists internally within the module.

Default values for parameters that have a choice list must be either blank or one of the values from the choice list. Any other setting results in an error message. If no default for a choice list is provided, the first entry on the list will be the default.

The default value may use substitution variables, just like the rest of the command line. So a valid default for an output file might be `<input.filename_basename>.foo`, meaning that the output file will have the same stem as the input.filename parameter, but will have a .foo extension.

- **Optional.** Select the check box to indicate that the parameter is optional. Optional parameters do not have to be specified on the command line. When a user fails to enter a value for an optional parameter, nothing is added to the command line for that parameter.

- **Prefix when specified.** If an optional parameter requires a text prefix on the command line, use this field to specify the prefix. For example, you might need to write "-F filename" to pass in a filename; however, if the filename is optional, you do not necessarily want to specify "-F". To solve this problem, set the prefix to "-F " (note that the ending space is included). If the optional filename is provided, then the prefix is also added.

- **Type.** Declaration of the type of an input parameter allows the GenePattern client to present the value to the user in the appropriate format. Parameter type choices are: text, integer, floating point, and input file. (If you specify an input file parameter, when a user runs the module and specifies the input file, GenePattern uploads the entire file to the server, not just the file name.)

- **File Format.** When you select a parameter type of input file, a drop-down list of file formats appears in the file format column. Select the valid file format(s) for this parameter. To select multiple file formats, use CTRL-click. If your module requires an input file format not included in the list, scroll back to the Output Description field and click New to add that format to the list.
**Adding Module Support Files**

When you create/update a module, you must specify all files used in your module, including scripts, libraries, property files, DLLs, executable programs, documentation, and so on. All files are copies to the GenePattern server and may be referenced in the command line field using the syntax: `<libdir>filename`. You can specify as many files as needed, provided you have the space available on your GenePattern server.

**Adding and Removing Support Files**

To specify a file, use the Support files field:

1. Click the Browse button next to an entry field to select a file. The Support files field provides five (5) entry fields, so you can enter at most five files at a time.
2. Click Save, near the bottom of the form. GenePattern saves all changes you have made to the module since you last saved, adds the files to the module and copies them to the server, creates a new version of the module, and displays the status message:
   
   Installation of your ModuleName module (version x) is complete.
   
   Run ModuleName

3. To continue editing the module, click your ModuleName in the first sentence. In the Create/Update Module form, the files that you added are now listed in the Current files field.
4. Repeat this procedure to add additional files.

To remove files that you have already added, use the Current files field:

1. Select the file from the Current files list.
2. Click Delete. Deleting a file from the Current files list deletes all changes since the last time you saved the module. The Web Client displays a warning message reminding you of this fact.
3. Click OK to delete the file (and any other changes made since the last time you saved).

**Including Documentation**

Public modules should always include documentation. Although GenePattern requires no special format, the GenePattern team suggests PDF files for maximum portability. The module documentation should include instructions for using the module, a detailed description of each input parameter, a detailed description of each output file (both its format and content), and explain the algorithm or reference the paper, journal, or book that explains it.

The documentation that you provide with your module is automatically available to GenePattern users. As a GenePattern user, when you select a module in GenePattern client, the client displays a form that includes the module parameters and a Help button. When you click the Help button, GenePattern examines the list of support files for the module and displays the first file that has a standard documentation extension. If you have provided a documentation file with your module, that file is displayed as the help file; if you have not provided a documentation file, GenePattern displays a message indicating the no information is available. (By default, the standard documentation file extensions are .doc, .pdf, .txt, .html, and .rdf. You can modify this list of extensions by editing the files.doc property in the GenePattern /resources/genepattern.properties file.)

**Creating Modules**

Creating a GenePattern module is a two-step process:

1. Write a program that executes the desired function. You can write the program in the language of your choice; for example, you can use a compiled language, such as C, to create an executable or use a scripting language, such as Perl, to create a script that is runs by an interpreter. The GenePattern Programmer's Guide provides guidelines for writing programs that will be run as GenePattern modules.
2. Use the GenePattern Web Client to create a GenePattern module that invokes the program that you have written. It takes just a few minutes to enter the necessary information. Once you have done so, you can run the module and share it with others. You can decide which parameters from the algorithm to expose to the user and can replace command line parameter names that are hard to remember with names that are self-explanatory. You can also create drop-down list choices for parameters to reduce the possibility of invoking the module with incorrect values.

To create a module that invokes the program that you have written (or otherwise obtained):

1. Click Modules & Pipelines>New Module. The Web Client displays the Create Module form:
2. Enter values for the fields. For descriptions of the fields, click Help or see the Module Definition Page.

3. Click Save to create the module. GenePattern checks the following:
   - Every parameter not marked as optional is included in the command line.
   - Every parameter in the command line parameter is a parameter, environment variable, or system property.
   - Module parameter names are valid.

   If no errors are found, GenePattern copies the support files to the server and makes the module available to the GenePattern clients.

   **Note:** By adding a module, a user can execute arbitrary code on the GenePattern server. Because arbitrary code may include malicious code, take precautions to protect your server: for example, employ virus scanner software and restrict access to appropriately privileged (non-root) users. For more information about securing your server, see Securing the Server.

**Tutorial: Creating a Module**

Following is a brief tutorial that creates a module named `log_transform`. The program invoked by this module is a Perl script, `gp_tutorial_files/log_transform/log_transform.pl`, which log-transforms all positive values in a data set and sets all negative or zero values to zero. This Perl script is part of the GenePattern tutorial data set, which is downloaded during a full installation of GenePattern and is also available on the GenePattern web site.

To create the `log_transform` module:

1. Click Modules & Pipelines>New Module. The Web Client displays the Create Module form. (The module definition form, with the tutorial data filled in, appears at the end of the procedure.)

2. Enter the following information in the first few fields:
   - **Name:** LogTransform
   - **Description:** Log transform a data (gct) file.
3. Enter the following text in the Command line field (if you are working online, cut and paste this text into the field):

```
<perl> <libdir>log_transform.pl -F <input.filename> -o <output.file>
```

Typically, you enter the command line as a combination of fixed text and variables defined by GenePattern. This allows the command line to be independent of the operating environment and allows different values to be specified at different invocations of the command. This command line uses the following variables:

- `<perl>` represents the full path to the Perl installation used by GenePattern.
- `<libdir>` represents the full path to the directory that contains the files for this module, including the program file.
- The Perl script, `log_transform.pl`, expects two parameters, an input file and an output file name: `-F <input.filename> -o <output.file>`. When your program has parameters, you include them in the command line and also define them in the Parameters field, as described below.

4. Enter the following information in the next few fields:

- **Module category**: Preprocess & Utilities
- **CPU type**: Any
- **Operating system**: Any
- **Language**: Perl
- **Version comment**: Initial version
- **File format(s)**: Select gct from the list of formats.

5. Use the Support files field to upload your program, any other files needed to execute the module, and documentation for the module (a file with a text extension, such as .pdf, .doc, or .txt):

1. Click the Browse button at the end of the first line in the Support files field. The Web Client displays the File Upload window.
2. Navigate to the `gp_tutorial_files/log_transform` directory, select the file `log_transform.pl`, and click Open. This is the script that implements the module.
3. Click the Browse button at the end of the second line in the Support files field. The Web Client displays the File Upload window.
4. Select the file `LogTransform.pdf` and click Open. This is the documentation for the module. When a GenePattern user displays your module and clicks the Help button, GenePattern displays the support file that has a text extension (such as .pdf .doc, or .txt).

6. Use the Parameters field to describe your two program parameters: input.filename and output.file. The parameter names and descriptions that GenePattern displays when a user runs your module are the parameter names and descriptions that you provide here.

In the first row of the Parameters field, enter the following information for input.filename:

- **name**: input.filename
- **description**: The dataset to be transformed (gct format).
- **type**: choose input file
- **file format**: choose gct

In the second row, enter the following information for output.file:

- **name**: output.file
- **description**: The name of the new transformed file.
- **type**: choose text (this is a name that the user enters)
7. Click Save. The Web Client displays a message informing you that the module has been saved.

8. Run the module to confirm that it has been added to the GenePattern server correctly.

Editing Modules

To edit a module:

1. Click Modules & Pipelines to display the Web Client start page.

2. Display a module definition form in one of the following ways:
   - Select a module that you created. When the Web Client displays the module parameters, click Edit.
   - Select a public module. When the Web Client displays the module parameters, click Properties. On the module definition form, click Clone to create a copy of the module. You created the copy, so you can edit it.

3. Edit the module definition form. Click Help for descriptions of the fields.
4. Click **Save** to create a new version of the module.

## Working with Pipelines

A GenePattern pipeline defines a sequential series of modules to be run. Modules run from a pipeline work exactly the same as those run directly from the Web Client. If you are unfamiliar with GenePattern pipelines, see the [Concepts Guide](#).

The following table summarizes the different ways you can work with GenePattern pipelines.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display pipeline definitions</td>
<td>A pipeline’s definition lists the pipeline’s author, the modules to be run and their parameters. To display the pipeline definition, click <strong>Modules &amp; Pipelines</strong> and select the pipeline. When the Web Client displays the pipeline parameters, click <strong>Properties</strong>. The Web Client displays the pipeline definition page.</td>
</tr>
</tbody>
</table>
| Share pipelines with other users | Zip files provide a convenient way to share pipelines with other GenePattern users.  
  - To export a pipeline to a zip file, click **Modules & Pipelines** and select the pipeline to export. When the pipeline parameters (if any) appear in the center pane, click **Export**.  
  - To install a pipeline from a zip file: click **Modules & Pipelines>Install from zip**.  
  For more information, see [Exporting and Installing Modules & Pipelines Using Zip Files](#). |
| Install pipelines from the repository | The Broad Institute maintains a repository of modules, pipelines, and suites. To install pipelines from the Broad repository, click **Modules & Pipelines>Install from Repository**. For more information, see [Installing Modules & Pipelines from the Repository](#). |
| Create pipelines | You can create an empty pipeline and add modules to it, or you can start with an analysis results file and have GenePattern create a pipeline that recreates that analysis results file. For more information, see [Creating Pipelines](#). |
| Edit pipelines | You can edit a pipeline that you have created or clone a public pipeline and edit your copy of the public pipeline. For more information, see [Editing Pipelines](#). |
| Delete pipelines | To delete a pipeline from your GenePattern server, click **Modules & Pipelines>Manage**. For more information, see [Managing Modules & Pipelines](#). |

### Pipeline Definition Page

To display the definition of a module:

1. Click **Modules & Pipelines** to display the Web Client start page.
2. Select the pipeline to display.
3. When the Web Client displays the module parameters, click **Properties**. The Web Client displays the pipeline definition page, as shown below.
On the pipeline definition page, you can:

- Click the icon next to a module to show/hide the module parameters.
- Click open all and close all to show and hide all module parameters.
- Click Clone to create (and edit) your own copy of this pipeline.
- Click Run to run the pipeline.
- Click Edit to edit the pipeline. The Edit button, not shown here, is only available for pipelines that you have created.

**Creating Pipelines**

To create a pipeline:

1. Display a pipeline definition form in one of the following ways:
   - To create an empty pipeline, click Modules & Pipelines> New Pipeline. The Web Client displays an empty pipeline definition form, as shown in the first figure below.
   - To create a pipeline based on an analysis results file, click the icon next to the analysis results file and select Create Pipeline from the pop-up menu. The Web Client displays a populated pipeline definition form, as shown in the second figure below.
   - To create a copy of an existing pipeline, click Modules & Pipelines and select the pipeline. When the Web Client displays the pipeline parameters, click Properties. On the pipeline definition form, click Clone to create
2. Complete the pipeline definition by editing the pipeline definition form, as described in Editing Pipelines.

3. Click Save to create the pipeline.

When you create an empty pipeline, the Web Client displays an empty pipeline definition form:

When you create a pipeline from a results file or by cloning, the Web Client displays a populated pipeline definition form:
Editing Pipelines

To edit a pipeline:

1. Click Modules & Pipelines to display the Web Client start page.

2. Display a pipeline definition form in one of the following ways:
   - Select a pipeline that you created. When the Web Client displays the pipeline parameters, click Edit.
   - Select a public pipeline. When the Web Client displays the pipeline parameters, click Properties. On the pipeline definition form, click Clone to create a copy of the pipeline. You created the copy, so you can edit it.

3. Edit the pipeline definition, as described below.

4. Click Save to create a new version of the pipeline.

The remaining topics in this section describe how to edit the pipeline definition:

- Editing the Pipeline Description
- Adding Modules
- Removing Modules
- Reordering Modules

**Editing the Pipeline Description**

The fields at the top of the pipeline definition form describe the pipeline:

- **Pipeline name**: The name of the pipeline. When naming pipelines, note the following:
  - Pipeline names can include alphanumeric characters, periods (.), and underscores (_).
  - Avoid special characters in pipeline names, such as: exclamation points (!), at signs (@), pound signs (#), dollar signs ($), percent signs (%), carets (^), ampersands (&), and asterisks (*).
  - For cross-platform compatibility, avoid the following names: con, prn, aux, nul, com1, com2, com3, com4, lpt1, lpt2, and lpt3. Machines running Windows cannot accept files with these names, regardless of the file extension.
  - GenePattern does not prevent you from using the same name for multiple pipelines; however, using unique names is strongly recommended.
● **Version:** To the right of the name field is a drop-down list of versions. By default, you are editing the most recent version of the pipeline. To edit a different version, select that version from the drop-down list.

Editing a pipeline creates a new version of the pipeline; it does not change the existing version of the pipeline. If you are unfamiliar with GenePattern versioning, see the Concepts Guide.

● **Description:** A brief description of the pipeline, which is displayed when a user runs the pipeline or views the pipeline definition.

● **Author:** The author's name and affiliation (company or academic institution). This is a comment-only field. If you share this pipeline, the author field allows other users to credit the author and to contact the author with questions, suggestions, or enhancement ideas.

● **Privacy:** Select Private (default) or Public. A private pipeline can be accessed only by the person who created or installed the pipeline (or by an administrator); a public pipeline can be seen and run by all users.

● **Version comment:** A brief description of this version. When GenePattern clients display a drop-down list of versions, the comments for each version are visible in the drop-down list.

● **Documentation:** The full path name of the file that contains the pipeline documentation. Documentation is strongly encouraged for public pipelines. Click **Browse** to select the (previously created) pipeline documentation file.

● **LSID:** The Life Science Identifiers (LSIDs) for this pipeline. You cannot create or edit LSIDs. The GenePattern server automatically assigns an LSID to each version of a pipeline. If you are unfamiliar with GenePattern versioning, see the Concepts Guide.

### Adding Modules

Each module in a pipeline has its own definition; for example:

1. Select the **Add Another Module** button. The Web Client starts a new module definition **after** the current module:

   ![Module Definition Form](image)

   **Note:** The only module in a new empty pipeline definition is the start of the first module.

2. Select a category of module from the **Category** list. The Web Client displays a drop-down list of modules in that category:

   ![Module Category List](image)

3. Select a module from the drop-down list of modules. The Web Client displays the definition form for that module:

   ![Module Definition Form](image)
4. At the top of the module definition form is the module name, followed by a drop-down list of versions. By default, you are using the most recent version of the module. To have the pipeline run a different version of the module, select that version from the drop-down list.

5. Enter the parameter values for the module. For most parameters, you enter a value, select a value from a drop-down list, or use the default value supplied by GenePattern.

To have GenePattern prompt the user for a parameter value when the pipeline is run:

1. Select the **Prompt when run** box to the left of the parameter field. The Web Client removes the parameter value from the pipeline definition.

2. Optionally, click **set prompt when run display settings** to modify the default text of the prompt.

For input file parameters, select a file or use an output file from a previous module:

- To select a file, click the **Browse** button to the right of the parameter field. The Web Client displays the Upload File window. Select a file and click **Open**. The selected file becomes the value for that parameter field.

- To have the input file be an output file generated by a previous module, choose a previous module from the **use output from** drop-down list. If the selected module generates multiple output files, the Web Client displays a drop-down list of the generated output files. Select the output file that you want to use.

The pipeline definition form has no mechanism for adding a module before an existing module; therefore, to add a module at the **beginning** of the pipeline: add the new_first module below the old_first module, delete the old_first module, and (if necessary) recreate the old_first module below the new_first module.

### Removing Modules

To remove a module, click the delete button for that module definition:
**Reordering Modules**

The pipeline definition form has no mechanism for reordering module. You must delete the module that you want to move and recreate it in its new position.

**Working with Suites**

Use suites to group modules and pipelines into packages that have related functionality; for example, you might create a suite that contains the modules that you most commonly use to analyze new data files. Suites help you to organize and work with modules and pipelines. If you are unfamiliar with GenePattern suites, see the Concepts Guide.

The following table summarizes the different ways you can work with GenePattern suites.

<table>
<thead>
<tr>
<th>Display suite definitions</th>
<th>To display the suite definition:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1. Click Suites&gt;Manage.</td>
</tr>
<tr>
<td></td>
<td>2. Click the name of the suite that you are interested in.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Share suites with other users</th>
<th>Zip files provide a convenient way to share suites with other GenePattern users.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• To export a suite to a zip file, click Suites&gt;Manage, click the icon next to a suite to display the suite menu, and select Export Including dependents or Export excluding dependents.</td>
</tr>
<tr>
<td></td>
<td>• To install a suite from a zip file: click Suites&gt;Install from zip.</td>
</tr>
<tr>
<td></td>
<td>For more information, see Exporting and Installing Suites Using Zip Files.</td>
</tr>
</tbody>
</table>

| Install suites from the repository | The Broad Institute maintains a repository of modules, pipelines, and suites. To install suites from the Broad repository, click Suites>Install from Repository. For more information, see Installing Suites from the Repository. |

| Create suites | To create a suite, click Suites>New. For more information, see Creating Suites. |

| Edit suites | You can edit a suite that you have created or copy a public suite and edit your copy of the public suite. For more information, see Editing Suites. |

| Delete suites | To delete a suite from your GenePattern server, click Suites>Manage. For more information, see Managing Suites. |

**Suite Definition Page**

To display the definition of a suite:

1. Click Suites>Manage.
2. Click the name of the suite that you want to display. The Web Client displays the suite definition page, as shown below.
● **Name:** The name of the suite.

● **Description:** A brief description of the suite.

● **Author:** The author's name and affiliation (company or academic institution). This is a comment-only field.

● **Privacy:** Select Private (default) or Public. A private suite may be accessed only by the person who created or installed the suite (or by an administrator); a public suite can be accessed by all users.

● **Support files:** Any files included with the suite. Public suites generally include documentation.

● **Modules & Pipelines:** The remainder of the definition form lists all of the modules and pipelines that are on your GenePattern server by category. The ClusteringSuite in this figure contains modules from only one category, the Clustering category.

From the suite definition page, you can:

● Click the icon next to the suite name to display the suite menu.

● Click open all and close all to show and hide the modules/pipelines in all categories.

● Click the icon next to a category to show/hide the modules/pipelines in that category.

### Creating Suites

To create a suite:

2. Define the suite by entering values for each field (see Suite Definition Page). To add modules and pipelines to the suite:
   
   ▪ Select the check box next to a module/pipeline to add that module/pipeline to the suite.

   ▪ Select the check box next to a category name to add all modules and pipelines in that category to the suite.

3. Click Save. GenePattern creates the suite.
Editing Suites

To view or edit a suite:

1. Click Suites>Manage. The Web Client displays the Manage Suites page, which lists the suites on your GenePattern server.
2. To view the suite definition, click the suite name.
3. To edit the suite definition:
   1. Click the icon next to the suite name and select Edit.
   2. Edit the suite definition.
   3. Click Save to update the suite definition.

Managing Modules, Pipelines, and Suites

An analysis module runs a single analysis. A pipeline runs a series of analysis modules. Suites group modules and pipelines into packages that have related functionality, which helps you to organize and work with modules and pipelines. If you are unfamiliar with GenePattern modules, pipelines and suites, see the Concepts Guide.

- Installing Modules & Pipelines from the Repository
- Exporting and Installing Modules & Pipelines Using Zip Files
- Managing Modules & Pipelines
- Installing Suites from the Repository
- Exporting and Installing Suites Using Zip Files
- Managing Suites

Installing Modules & Pipelines from the Repository

The Broad Institute maintains a repository of modules and pipelines that are freely available to the public. To install these modules and pipelines on your GenePattern server:
1. Click Modules & Pipelines>Install from Repository. The Web Client displays the Install Modules & Pipelines from Repository page, as shown below.

2. Select the modules and pipelines to install.

   The search fields at the top of the page allow you to select any version of a module that is not installed on your server or more recent versions of any module already installed on your server. To install an older version of a module already installed on your server, delete the current version(s) installed on your server. You can then use this page to install any version of the module (which is no longer installed on your server).

3. Click Install Checked.

Use the top section of the form to find the modules to install. To update the list of modules/pipelines, select the modules/pipelines to search for and click Search:

- **Search for new modules to install**: Displays modules and pipelines that are in the Broad repository and not on your server.
- **Search for updates of the currently installed modules**: Displays modules and pipelines where the version in the Broad repository is more recent than the version on your server.
- Optionally, filter your search results by operating system platform:
  - **Platform independent**: Display only modules that run on any platforms (including Windows).
  - **Windows**: Display only modules that run on Windows.

For each module and pipeline, the Web Client displays similar information:

- Module/pipeline name.
- Drop-down list of available versions. By default, the most recent version is selected.
- Brief description of the module/pipeline.
- **documentation** link, which displays the module/pipeline documentation.
- **download zip** link, which downloads a zip file of the module/pipeline. Downloading the zip file allows you to examine the source files before installing them on your server. You can then install the module/pipeline from the zip file, as described in Exporting and Installing Suites Using Zip Files.
In the Module type column, the category label assigned to the module/pipeline.

In the Details column, the author, size, and operating system requirements for the module/pipeline.

Exporting and Installing Modules & Pipelines Using Zip Files

Zip files provide a convenient means of sharing your modules and pipelines with other GenePattern users. You can export a module or pipeline to a zip file. The zip file can then be used to install the module or pipeline on another GenePattern server.

To export a module or pipeline to a zip file:

1. Click Modules & Pipelines. The Web Client displays the start page.

2. In the Modules & Pipelines pane, select the module or pipeline to export. The analysis parameters (if any) appear in the center pane.

3. Click Export.

4. If you are exporting a pipeline, the Web Client displays the following dialog:

   - Click Include modules to create a zip file that includes all modules in the pipeline.
   - Click Pipeline only to create a zip file that contains only the pipeline definition. (If you install a pipeline without installing the modules that it uses, when you run the pipeline, GenePattern lists the missing modules and prompts you to edit the pipeline or install the modules.)

5. After creating a zip file that contains the module/pipeline, the Web Client displays the following dialog box:

6. Click OK to save the zip file to your local drive.

To install a module or pipeline from a zip file:

1. Click Modules & Pipelines>Install from zip. The Web Client displays the Install Modules & Pipelines page, as shown below.

2. Select the file to install in one of two ways:
   - To select a zip file from a directory, click Browse.
• To select a zip file from a web site, enter the URL for the zip file.

3. Use the Visible to radio buttons to select a private or public installation:
   • Your user name: Choose this option for a private installation. Only you (or an administrator) can view and run the module/pipeline.
   • All users (default): Choose this option for public installation. Any user connected to this server can view or run the module/pipeline.

4. Click Install.

Managing Modules & Pipelines

Click Modules & Pipelines>Manage to display the Manage Modules & Pipelines page. From this page, you can

• View the modules/pipelines installed on your GenePattern server.
   
   To view only your own modules and pipelines, clear the show everyone’s modules check box. To view all modules and pipelines, select this check box.

• Delete modules/pipelines from your GenePattern server.

   Note: If the check box next to the module/pipeline is grayed out, you cannot delete it. Typically, this occurs when the module/pipeline is used by another module, pipeline, or suite. To delete the module/pipeline, you must first delete the module, pipeline, or suite that uses it or remove it from that module, pipeline, or suite.
Installing Suites from the Repository

The Broad Institute maintains a repository of suites that are freely available to the public. To install these suites on your GenePattern server:

1. Click Suites>Install from Repository. The Web Client displays the Install Suites from Repository page, as shown below.
2. Select the suites to install.
3. Click Install Checked.
Use the top section of the form to find the suites to install. To update the list of suites, select the suites to search for and click Search:

- **Search for new suites to install**: Displays suites that are in the Broad repository and not on your server.
- **Search for updates of the currently installed suites**: Displays suites where the version in the Broad repository is more recent than the version on your server.

For each suite, the Web Client displays similar information:

- **Suite name**: Click the icon next to the name to display a menu of commands for working with the suite (see [Suites Menu](#)).
- **Drop-down list of available versions**: By default, the most recent version is selected.
- **One-line description of the suite**.
- **download zip link**, which downloads a zip file of the suite. Downloading the zip file allows you to examine the source files before installing them on your server. You can then install the suite from the zip file, as described in [Exporting and Installing Suites Using Zip Files](#).
- **In the Modules column**, a list of the modules and pipelines in the suite.

### Exporting and Installing Suites Using Zip Files

Zip files provide a convenient means of sharing your suites with other GenePattern users. You can export a suite to a zip file. The zip file can then be used to install the suite on another GenePattern server.

To export a suite to a zip file:

1. Click **Suites>Manage**.
2. Click the icon following the name of the suite that you want to export. The Web Client displays the suite menu.
3. Click one of the following:
   - **Export excluding dependents**: Creates a zip file that contains the definition of the suite, but not the modules or pipelines in the suite. Installing the suite from this zip file will not install any modules or pipelines in the suite; they must already be installed on the GenePattern server or be installed separately.
• **Export Including dependents:** Creates a zip file that contains the definition of the suite, as well as the modules and/or pipelines in the suite. Installing the suite from this zip file will also install the modules and pipelines in the suite (unless they are already installed on the GenePattern server).

To install a suite from a zip file:

1. Click **Suites>Install from zip.**
2. Select the file to install. You can identify the zip file using a file specification or a URL.
3. Use the **Visible to** radio buttons to select a private or public installation:
   - Your user name: Choose this option for a private installation. Only you (or an administrator) can view and run the module/pipeline.
   - All users (default): Choose this option for public installation. Any user connected to this server can view or run the module/pipeline.
4. Click **Install.**

### Managing Suites

Click **Suites>Manage** to display the Manage Suites page. From this page, you can

- View the suites installed on your GenePattern server.
- Delete suites from your GenePattern server. If the check box next to the module/pipeline is grayed out, you cannot delete it.
- Click the icon next to a suite name to display a menu of commands for working with the suite (see **Suites Menu**).
Managing the GenePattern Server

GenePattern can be run standalone on a small machine or separated into its client and server components to take advantage of a more powerful compute server. When you installed your GenePattern server, you set the basic server configuration options for your site. This section describes how to modify GenePattern server configuration options and how to manage other aspects of the GenePattern server environment:

- Modifying Server Settings
- Using a Queuing System
- Securing the Server

Modifying Server Settings

To modify the configuration of your GenePattern server, use the Server Settings page:

1. Click Administration>Server Settings to display the Server Settings page.
2. From the Server Settings pane, select the server setting that you want to modify. The Web Client displays a page of related server configuration options.
3. Modify and save the server configuration options.
4. Optionally, return to step 2 to change additional settings.

The following table summarizes the server settings. For more detail, click a link in the table.

<table>
<thead>
<tr>
<th>Access</th>
<th>Specify which clients have access to the server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Advanced</td>
<td>Specify software source directories and other low-level configuration options.</td>
</tr>
<tr>
<td>Command Line Prefix</td>
<td>Specify commands and qualifiers to be prepended to the command line used to invoke a module or pipeline.</td>
</tr>
<tr>
<td>Custom</td>
<td>Create new server configuration options.</td>
</tr>
</tbody>
</table>
Database Specify configuration options for the GenePattern database.

File Purge Specify how long files remain on the server before being deleted.

GenePattern Log Display the log file for the GenePattern server.

Java Flag Specify the Java flags to be added to Java command lines executed by the server.

LSID Specify the server portion of the LSID and show/hide LSIDs in the Web Client.

Programming Languages Specify the root directories for the programming languages used by GenePattern.

Proxy If your organization has a web proxy between the GenePattern server and the internet, specify the proxy information required to access the internet.

Repositories Specify the URL used to access the module repository and the suite repository.

Shut Down Server Shutdown the GenePattern server.

Web Server Log Display the log file for the web server used by the GenePattern server.

Access
Use the Access page to define which GenePattern clients have access to the GenePattern server. The localhost (127.0.0.1) computer cannot be denied access to the locally installed GenePattern server. This prevents you from inadvertently denying yourself access to the server.

Using the Access page to control which computers have access to the GenePattern server is the simplest way to secure your server. You can also control access to your server based on user authentication and user permissions, as described in Securing the Server. The Access page filters are applied before any user-specific authentication or permissions are checked. If your computer cannot access the server, you cannot access the server regardless of your username/password or permissions.

- Click **Standalone** to allow only local clients to connect to the server; that is, you can access this GenePattern server only from the computer that it is running on.
- Click **Any Computer** (default) to allow any client to connect to the server.
- Click **These Domains** to allow only clients from specific domains to connect to the server. Enter a comma-separated list of domains or IP addresses in the text box, for example: broad.mit.edu,dfci.harvard.edu,mit.edu.

GenePattern scans all incoming connection attempts. If they match in whole or in part any domain name or IP address in this list, the server allows access; otherwise, the server redirects the connection to a page indicating that the server does not allow access.

Click Save to save your changes. Click Restore to return to the value set at installation.

Advanced
The Advanced page contains directory specifications for the GenePattern source files and other low-level configuration options. You rarely need to modify these options.
Click Save to save your changes. Click Restore to return to the values set at installation.

**Command Line Prefix**

Use the Command Line Prefix page to define commands and qualifiers to be prepended to the command line used to invoke a module or pipeline. For example, use this page to prepend commands and qualifiers that execute modules and pipelines on a cluster farm, as described in *Using a Queuing System*.

To prepend text to all (or most) command lines executed by the GenePattern server:

1. Enter the desired commands and qualifiers in the **Default Command Prefix** field.
2. Click **save default**. GenePattern displays the updated content of the **default** prefix. The name/content table in the middle of the form lists the **default** prefix and its content. The previous illustration shows the **default** prefix with no content.

When GenePattern executes a module or pipeline, it constructs the appropriate command line, prepends the **default** prefix to that command line, and then executes the command line.
To prepend text only to command lines that invoke specific modules or pipelines:

1. In the Add New Prefix field, enter a name for the prefix and the commands and qualifiers to prepend to the command line.
2. Click add prefix. GenePattern creates the new prefix, updates its content, and adds the prefix to the name/content table in the middle of the form.
3. At the bottom of the form, select one or more module(s)/pipeline(s), select your new prefix, and click add mapping. GenePattern adds the prefix information to the module/command prefix name table.

When GenePattern executes a module or pipeline listed in the module/command prefix name table, it constructs the appropriate command line, prepends the specified prefix to that command line, and then executes the command line. (When GenePattern executes a module or pipeline not listed in that table, it constructs the appropriate command line, prepends the default prefix to that command line, and then executes the command line.)

Custom

Use the Custom page to define your own configuration options.

When you create a module, the custom configuration options are available as substitution variables in the module command line. For example, if you define a custom property "foo", you can use <foo> in the command line to pass the value of the custom configuration option to your module. In the Broad repository, for example, the LandmarkMatching and PeakMatch modules use the custom configuration option pepperPrefix.

```
<table>
<thead>
<tr>
<th>Custom Settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
</tr>
<tr>
<td>------</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
```

1. In the name field, enter a name for the configuration option.
2. In the content field, enter a value for the configuration option.
3. Click add setting. GenePattern adds the option to the table at the bottom of the form.

Database

Use the Database page to set configuration options for the GenePattern database. The following figure shows the HSQL options. You rarely need to change these options.

```
<table>
<thead>
<tr>
<th>Database Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database:</td>
</tr>
<tr>
<td>Hibernate Driver Class:</td>
</tr>
</tbody>
</table>
| Hibernate URL:       | jdbc:hsqldb:hsql://127.0.0.1:901/
| Hibernate User Name: | sa                 |
| Hibernate Password:  |                    |
| Hibernate Dialect:   | org.hsqldb.Dialect  |
| Hibernate Shutdown:  | true               |
| HSQL Port:           | 901                |
| HSQL Class:          | org.hsqldb.Server |
| HSQL Args:           | port=901 -database=FILE |resources|Gene |
| HSQL Scheme:         | analysis_hypersonic |
```

Click Save to save your changes. Click Restore to return to the value set at installation.

File Purge

Use the File Purge page to specify when analysis results files are deleted from the server:
● Use **Purge Jobs After** to specify the number of days the server keeps the analysis results files. To prevent the server from automatically deleting the files, set this value to -1.

● Use **Purge Time** to specify what time of day (24-hour format) the server deletes the files.

Click Save to save your changes. Click Restore to return to the values set at installation.

**GenePattern Log**

Use the GenePattern Log page to view warnings and messages generated by the GenePattern server. (Use the **Web Server Log** page to view messages generated by the web server that GenePattern uses.)

**Java Flag**

Use the Java Flag page to add Java virtual machine configuration parameters (such as VM memory settings) for the execution of Java-based modules:

● Use **Java Flags** to add flags to Java command lines executed on the GenePattern server.

● Use **Visualizer Java Flags** to add flags to Java command lines executed on the GenePattern client.

● Use **R Java Flags** to add flags to Java command lines executed in the R programming environment.

Click Save to save your changes. Click Restore to return to the values set at installation.

**LSID**

If you are unfamiliar with GenePattern versioning and Life Science Identifiers (LSIDs), see the Concepts Guide.

● Use **LSID Authority** to identify your GenePattern server. The server identifier is incorporated into every LSID.

● Use LSID Show to determine whether to show or hide LSIDs on forms in the Web Client.

Click Save to save your changes. Click Restore to return to the values set at installation.
Programming Languages

Use the Programming Languages page to specify the root directories for the programming languages used by GenePattern:

When you install GenePattern, you install the programming languages used by GenePattern. If you have alternate programming language installations that you prefer to use, use this page to point to those installations.

Click Save to save your changes. Click Restore to return to the value set at installation.

Proxy

If your server is behind a firewall, use the Proxy page to set the HTTP and FTP Proxy information. Without the proxy information, the server cannot download modules, pipelines, or suites from the repository maintained by the Broad Institute. If you do not know the proxy information, contact your systems administrator.

Click Save to save your changes. Click Restore to return to the values set at installation.

Repositories

Use the Repositories page to identify the location of the repository to be accessed by the GenePattern server when you install modules and pipelines or suites from the repository. By default, it points to the module repository maintained by the Broad Institute. If you would like to implement and maintain a module repository at your site, contact the GenePattern help desk (gp-help@broad.mit.edu).

Click Save to save your changes. Click Restore to return to the values set at installation. Click Remove to delete the selected URL.
Shut Down Server
You can shutdown the GenePattern server by clicking the link on this page. For easier ways of shutting down the server, see Exiting from GenePattern.

Web Server Log
Use the Web Server Log page to view messages generated by the web server that GenePattern uses. (Use the GenePattern Log page to view warnings and messages generated by the GenePattern server.)

Using a Queuing System
This section describes how you can integrate the GenePattern server with your queuing system. If you need help integrating the GenePattern server into your environment in other ways, contact the GenePattern help desk (gp-help@broad.mit.edu).

Queueing systems such as the Load Sharing Facility (LSF) and the Sun Grid Engine (SGE) allow computational resources to be used effectively. If you have such a queuing system, you typically want the GenePattern server to use it. To configure your GenePattern server to execute jobs using LSF or SGE:

- Add the GenePatternURL property to the GenePattern configuration file, GenePatternServer/resources/genepattern.properties, specifying the URL of your server.
  
  For example:
  
  GenePatternURL=http://myserver.company.com:8080/gp/

  When you run a pipeline, the GenePattern server uses this URL to construct the links to the output files.

  By default, the GenePatternURL property is not set. When you run a pipeline, the GenePattern server derives the URL at run time based on the current IP address of the host server. This is ideal for a user running on a laptop, where the IP address may change at startup. However, if you are using a queuing system, the derived URL is incorrect: it is based on the IP address of the queuing system server rather than the GenePattern server.

- Use the Command Line Prefix options of the Server Settings page to have the GenePattern server add the required options to the command line each time it executes a module.

  For example, if you are using LSF, modify the Command Line Prefix options as follows:

  1. Click Administration>Server Settings to display the Server Settings page.
  3. Enter the following text in the Default Command Prefix field:

     bsub -K -o lsf_log.txt

     - The –K flag instructs the bsub command to wait for the job to complete before returning.
     - The –o flag specifies the file to which the job writes standard output and standard error messages.
  4. Optionally, set the environment variables BSUB_QUIET and BSUB_QUIET2 to prevent bsub from printing common job messages to standard out:

     - Setting BSUB_QUIET prevents bsub from printing the messages <<Job is submitted to default queue <normal>> and <<Waiting for dispatch>>.
     - Setting BSUB_QUIET2 prevents bsub from printing the message <<Job is finished>>.
Note: When using a queuing system, short jobs will take slightly longer because they must be dispatched to the queuing system. However, on a heavily used server, using a queuing system to manage job executions should improve performance overall, especially for compute-intensive and long-running jobs.

Securing the Server
Securing your GenePattern server helps you to control who has access to which operations. Since GenePattern is primarily a web application (including SOAP interfaces) running on a web server, general approaches for securing your web servers are applicable to your GenePattern server. In addition, GenePattern provides several security features that can easily be used by non-technical users to control access to the server.

This section describes several ways to secure your GenePattern server:
- Access Filtering
- Password Protection
- User Authentication
- User Permissions
- Secure Sockets Layer (SSL) Support

Access Filtering
Use the Access page to define which GenePattern clients have access to the GenePattern server. The localhost (127.0.0.1) computer cannot be denied access to the locally installed GenePattern server. This prevents you from inadvertently denying yourself access to the server.

Access filtering prevents users from connecting to your GenePattern server unless they come from a known computer. This is the simplest way to secure your GenePattern server because you control access filtering from the Server Administration page of the Web Client. The Access page filters are applied before any user-specific authentication or permissions are checked. If your computer cannot access the server, you cannot access the server regardless of your username/password or permissions.

To use access filtering (as described in Modifying Server Settings):
1. Click Administration>Server Settings.
2. Use the Access page to determine which clients have access to your GenePattern server:
   - Click Standalone to allow only local clients to connect to the server; that is, you can access this GenePattern server only from the computer that it is running on.
   - Click Any Computer (default) to allow any client to connect to the server.
Click These Domains to allow only clients from specific domains to connect to the server. Enter a comma-separated list of domains or IP addresses in the text box, for example: broad.mit.edu,dfci.harvard.edu,mit.edu.

GenePattern scans all incoming connection attempts. If they match in whole or in part any domain name or IP address in this list, the server allows access; otherwise, the server redirects the connection to a page indicating that the server does not allow access.

**Password Protection**

By default, your GenePattern server requires only a user name to authenticate a GenePattern user. You can easily add password protection by modifying the GenePattern server properties.

To add password protection to your server, modify the GenePattern server properties:

1. Edit the GenePattern configuration file, GenePatternServer/resources/genepattern.properties.
2. Set the requirePassword property to true: requirePassword=true.
3. Save the genepattern.properties file.
4. Restart the GenePattern server.

Initially, the password associated with your user name is blank. To change your password, start the Web Client and select My Settings.

**User Authentication**

The GenePattern server can be configured to provide user name and password protection. Alternative user authentication can easily be added by any capable Java programmer at your site. The remainder of this section is written for such a programmer.

GenePattern user authentication is performed by a servlet filter installed in front of the GenePattern web application in its web.xml file. To implement alternative authentication, you need to implement a new servlet filter that performs the desired authentication and a new login page that requests additional information from the user. The new servlet filter must, after authenticating a user, set a session attribute in the java.servlet.http.HttpSession object called userID. All pages in the GenePattern server and all database interactions will use this as the user's user name.

To see the source code for the default AuthenticationFilter.java and the web.xml files, click the following links: AuthenticationFilter.java, web.xml.

Once you have written and compiled the new ServletFilter:

1. Place the jar file containing the new ServletFilter into the following directory:
   */GenePatternServer/Tomcat/webapps/gp/WEB-INF/lib
   
   **Note:** It is important to maintain the existing order of the servlet filters in the web.xml document as they are used in the order they are defined in the document. The Authentication filter must come before the Authorization filter to work.
3. Change the definition of the AuthenticationFilter to use the class that you have provided.
4. Add any necessary configuration elements that it requires.
5. Restart the GenePattern server for the changes to take effect.

**Note:** If you look at the code for the default Authentication Filter (AuthenticationFilter.java), you will see that it allows requests through that have a parameter called jsp_precompile that have come from the localhost. If you do not allow these requests through unauthenticated, you will see a series of errors when you start the GenePattern server as it attempts to precompile the JSP pages. These are not fatal errors, but they slow down server response for users the first time that pages are accessed following a server restart.
**User Permissions**

The GenePattern server has a built-in authorization mechanism based on two configuration files in the `GenePatternServer/resources` directory:

- `userGroups.xml` defines user groups
- `permissionMap.xml` defines which user groups have which permissions

User authorization is based on the user’s identity as provided at GenePattern login (for more information, see User Authentication). Once a user has been authenticated, the GenePattern server uses these two configuration files to determine the user’s permissions. Keep file permissions applied to these files to ensure that they are not modified unintentionally.

The default configuration files allow all users to perform all actions: `userGroups.xml`, `permissionMap.xml`. One simple way to limit access to your server is to edit the `userGroups.xml` file and name your system administrators; for example: `userGroups.xml (modified)`.

**userGroups.xml**

The `userGroups.xml` file defines groups of users to whom permissions may be assigned.

Any number of groups may be created as long as their names are unique. If the user named * is included in a group, as shown in the default settings, then any and all users are considered to be a part of that group. A user may belong to any number of groups.

**permissionMap.xml**

The `permissionMap.xml` file maps permission names to user groups; that is, you use this file to state that members of a particular group have a particular permission.

- **Groups:** Any number of groups may be assigned a permission by adding additional `<group name="thename"/>` elements to a permission. The presence of a group named * means that any and all groups have that permission, which means any and all users have that permission.
- **Permissions:** Permissions are predefined by GenePattern and should not be added or removed. The following table describes the predefined permissions, which are listed in the default `permissionMap.xml` file and are the only permissions recognized by GenePattern.

**Note:** No explicit permission is required to run public modules/pipelines, or private modules/pipelines that you have created. No explicit permission is required to edit or delete your own modules, pipelines, suites, or jobs.

- `createModule` Permits creation of a module. Creation refers to any action that adds a module to the server, including create, install from repository, install from zip, and clone.
- `createPipeline` Permits creation of a pipeline. Creation refers to any action that adds a pipeline to the server, including create, install from repository, install from zip, and clone.
  **Note:** To install the modules in a pipeline, you must have `createModule` permission.
- `createSuite` Permits creation of a suite. Creation refers to any action that adds a suite to the server, including create, install from repository, install from zip, and clone.
  **Note:** To install the modules in a suite, you must have `createModule` permission.
- `adminJobs` Permits viewing and deleting jobs and associated files owned by other users.
- `adminModules` Permits viewing and deleting private modules owned by other users. Permits deleting public modules.
  **Note:** No explicit permission is required to view public modules.
- `adminPipelines` Permits viewing and deleting private pipelines owned by other users. Permits deleting public pipelines.
  **Note:** No explicit permission is required to view public pipelines.
- `adminSuites` Permits viewing and deleting private suites owned by other users. Permits deleting public suites.
Note: No explicit permission is required to view public suites.

**adminServer**
Permits access to Administration>Server Settings and all actions on the Server Settings page, including modifying server settings and shutting down the server.

**User Authorization**
GenePattern authorization, like GenePattern user authentication, is performed by a servlet filter installed in front of the GenePattern web application in its web.xml file. To implement alternative authorization, you need to implement a new servlet filter that performs the desired authorization. It is important to maintain the existing order of the servlet filters in the web.xml document as they are used in the order they are defined in the document. The Authentication filter must come before the Authorization filter for the Authorization filter to work. To see the source code for the default AuthorizationFilter.java and the web.xml files, click the following links: AuthorizationFilter.java, web.xml.

**Secure Sockets Layer (SSL) Support**
This section describes how you can modify the GenePattern web application to run on a web server that is configured to use the HTTPS protocol, where essentially the regular http requests are routed through a secure sockets layer (SSL) making them much harder for hackers to access. If you have installed your GenePattern server onto a web server other than the default Tomcat instance it is distributed with, configure your web server according to its instructions and then follow Step 2 below.

Note: When running under SSL, programming language clients and the GenePattern Desktop Client may not be able to connect to your GenePattern server.

**Step 1. Configure Tomcat for SSL support**
Follow the instructions available at [http://tomcat.apache.org/tomcat-5.5-doc/ssl-howto.html](http://tomcat.apache.org/tomcat-5.5-doc/ssl-howto.html) to configure the Tomcat instance for using SSL. In doing so, you will modify the Tomcat configuration file, which is located in the GenePatternServer/Tomcat/conf directory.

**Step 2. Configure GenePattern for SSL**
Once the Tomcat (or other web server) has been configured for SSL, modify the GenePattern configuration file, GenePatternServer/resources/genepattern.properties, to ensure that its properties are in synch with the web server:

1. Add a new key, `java.net.ssl.trustStore=<path to keystore>`,
   This should point to the keystore you created when configuring Tomcat (above) or some keystore that GenePattern can use to establish SSL connections.
2. Modify the value for the key `GENEPATTERN_PORT` to use the https port you selected when configuring Tomcat (above).
3. Modify the value for the key `GenePatternURL` to use the https protocol and the https port you selected, for example:

Save the genepattern.properties file and restart your server. Any bookmarked links to your GenePattern server must be updated to the new protocol and port.
